TITLE

WATER BASED PRIMER COMPOSITIONS

This invention claims the benefit of United States Provisional Application No. 60/058,719, filed September 12, 1997. .

BACKGROUND OF THE INVENTION

Field of the Invention

The subject invention pertains to an aqueous
5 primer containing a silane adhesion promoter for use on
metal surfaces to which composite or metal adherends
will be bonded utilizing structural adhesives. More
particularly, the subject invention pertains to a
primer comprising an aqueous dispersion of a solid
10 thermosetting resin, a silane adhesion promoter and a
solid curing agent which contain little or no volatile
organic solvent.

Description of the Related Art

15

In the current manufacture of composite
structures, particularly in the aerospace and
transportation sectors, it is frequently necessary to
bond a fabricated metallic structure to metal or
20 composite adherends utilizing structural adhesives,
generally structural film adhesives, or to laminate one

- 2 -

or more plies of thermosetting resin impregnated fibrous reinforcement to the fabricated metal structure. In general, to ensure the greatest level of adhesive strength, the metal surface(s) are

5 scrupulously cleaned of dirt, soil, grease, and metal oxidation products immediately prior to bonding. Unfortunately, this procedure cannot be generally used most times, as the cleaning and bonding operations are often separated by long periods of time. During such

10 periods, the metal surface may become hydrolyzed, lessening the adhesive strength of the bond. One alternative to overcome this difficulty is to use a primer on the cleaned metal surface. However, many of the commercially available primers do not provide the

15 desired durability or performance required when exposed to harsh environmental conditions.

Primers have often been prepared from one or two component thermosetting resins diluted to sprayable

20 levels with volatile organic solvents. However, the use of primers containing large amounts of volatile organic compounds ("VOCs") is under increasing scrutiny for both toxicological and environmental reasons.

25 It has been proposed to utilize electro-depositable primers. Such primers contain resin particles bearing a charged group which migrate to an oppositely charged substrate from aqueous solution or dispersion. Such compositions often contain a lower

30 but still undesirable level of VOCs and do not have ideal properties due to the restraints placed on the resin structure. Other ways of applying primers to metal surfaces include spraying, brushing or dipping the metal in a bath of primer.

35

In addition, liquid epoxy esters were proposed for use in coatings by C.K. Thorstad, "Emulsions--Why and How They are Used", *Modern Plastics*, pp. 83-84,

- 3 -

July 1995, in compositions containing either water or the liquid epoxy ester itself as a vehicle, together with polyvinylacetate, polyacrylic, or poly(butadiene/styrene) lattices. Acid curing agents, for example dimethyl acid pyrophosphate or boron trifluoride, are cited for use in these applications.

In U.S. Pat. No. 2,872,427 it has been proposed to utilize aqueous emulsions of liquid epoxy resins in textile treating. Additional suggested uses are in paints and enamels. The emulsions contain one or more emulsified liquid epoxy resins dispersed in an aqueous dispersing phase containing an alkali and acid stable non-ionic emulsifying agent and a water-dispersible binding colloid. For those applications where curing agents are also required, the curing agent is dissolved into the epoxy resin prior to dispersion. Such emulsions are storage stable with respect to sedimentation or coagulation, but suffer from the defect that since the epoxy and curing agent are intimately associated, premature curing may take place, particularly when exposed to elevated temperatures during shipment or storage. Shelf life of such emulsions is extremely limited. Furthermore, the protective colloids utilized are not themselves thermally stable, and may cause high temperature performance of the composition to suffer. Finally, such coatings suffer from lack of solvent resistance.

Raghavon and Lewis in the article "Epoxy Water-Borne Primer: Low-Temp Cure and Zero VOCs", *Modern Paint and Coatings*, July 1991, evidences the need for water-borne primers without VOCs and suggests use of an aqueous dispersion. However, no details of a suitable composition for such use are given.

U.S. Pat. No. 5,001,173 describes basecoats for metal surfaces which are to be latex primed and

- 4 -

5 painted. The basecoat comprises an aqueous epoxy resin dispersion also containing chromium trioxide and preferably phosphoric acid. The use of aromatic amine or other solid epoxy curing agents is not disclosed.

10 5 The basecoat is followed by a solvent borne primer containing substantial amounts of polyesters. In the article "Guidelines to Formulation of Waterborne Epoxy Primers", M.A. Jackson, *Polymer Paint Color Journal* 180, (4270), 1990 at pages 608-621 discloses two

15 10 component primer systems containing as one component an epoxy resin dispersion in water and solvent together with various corrosion inhibitors, and, as the second component, a water-reducible amine catalyst in water. Such formulations, however, require mixing or metering

15 of two separate components and are not storage stable.

In the article "Waterborne Epoxy Dispersions Provide Compliant Alternatives", R. Buehner et. al., *Adhesives Age*, December 1991, described waterborne

20 20 liquid and solid epoxy resin dispersions cured with dicyandiamide and water-soluble 2-methylimidazole catalyst for use as adhesives. However, the shelf life of such dispersions is indicated as only several days or less.

25 Another significant consideration in the use of primers is the durability and corrosion resistance of the joint formed between the metal surface and the material bonded to the metal surface. This is

30 30 particularly important in structural applications, such as aircraft structures, because these joints are exposed to a wide range of environmental conditions with extreme temperatures, high humidity, and highly corrosive marine environments. To avoid the failure of

35 35 the joint as well as to meet stringent commercial passenger and cargo aircraft standards, the adhesive-bonded joint of the structural component must withstand harsh environmental conditions, and, in particular,

- 5 -

resistance to corrosion and disbonding in humid, salt-laden environments, especially those resulting from sea spray or deicing materials. Failure of these joints often starts with diffusion of water through the adhesive followed by corrosion of the underlying metal structure. Thus, it is desirable to have a method and composition useful for bonding metal surfaces that delays onset of corrosion and exhibits stability in aqueous and salt-laden environments.

10

One method to improve the environmental durability of the metal interface in aerospace applications is etching the metal surface in acid and then anodizing it in phosphoric acid or chromic acid. This is particularly necessary for aerospace applications which involves protection of the aluminum oxide surface of aluminum adherends from moisture-induced hydrolysis. It has been found that aluminum substrates etched in acid and then anodized in phosphoric or chromic acid have shown superb environmental durability with either organic or aqueous based primers. However, if the metal surface is merely abraded, or only given the acid etch treatment, only the organic solvent-based primers show superior results. In the case of steel adherends the aqueous-based primers have been found to give unacceptable durability no matter how the surface is treated.

However, chromate and phosphate-based anodizing surface treatments have been found to have a number of disadvantages in that these processes typically use large amounts of water to neutralize the treated metal surfaces, and to rinse off the corrosive acids used for anodization of the metal surface. Disposal of the phosphate or chromate containing waste water is expensive and can be environmentally hazardous. Commercial anodizing processes also require large amounts of electricity to sustain an anodizing current

- 6 -

in the anodizing bath, particularly for large metal components, and require expensive equipment such as large anodizing and rinsing tanks, automatic systems for transferring the metal component from the anodizing tank to the rinsing tank, and sizable electrical power supplies. Thus, it is desirable to provide a bonding composition and method that does not use excessive amounts of water or electricity, and that can be used without large capital outlays for expensive equipment.

Another disadvantage of conventional treatment processes is their narrow processing window. Deviation from the processing window can result in poor bonding. For example, in phosphoric acid anodizing processes ("PAA"), if the metal component is not removed from the phosphoric acid bath immediately after the anodization current is turned off, the anodized oxide coating formed on the metal component can be rapidly dissolved by the corrosive chromic or phosphoric acid bath, resulting in a loosely bonded oxide coating. Thus, it is desirable to have a surface treatment process that provides a relatively large processing window to allow flexible production schedules while minimizing failure of the bonded joint.

Another significant disadvantage of conventional surface treatment processes arises from their use of highly toxic and hazardous chemicals, such as hexavalent chromium compounds. Disposal of the waste chromic byproducts, and the large amount of metal sludge dissolved in the acid, has become increasingly expensive in view of stringent environmental regulations and standards. Thus many conventional surface treatment processes are being gradually phased out because of the environmental regulations. Therefore, it is also desirable to have a non-toxic surface treatment process that is substantially environmentally benign.

- 7 -

It is well known in the prior art that silanes can be employed as primers in metal to metal or metal to rubber adhesive bonding. W. Bascom in the review article "Primers and Coupling Agents", Engineered Materials Handbook, Vol. 3, Adhesives and Sealants, page 254, 1990, describes the use of silanes as primers for adhesives; it also describes the addition of silanes to adhesives applied directly to metal or to primed surfaces. Unfortunately, it has been found that silane-based adhesion promoters fail to provide corrosion protection at or under the bond line unless the metal surface(s) is first pre-treated as by anodizing, phosphatizing, and the like. Corrosion prevention at the bond line is very desirable inasmuch as it leads to enhanced environmental resistance.

Silanes have been added to blends of solvents to make primers, and more recently, with the trend towards low or no VOC emissions, silanes have simply been added to water.

U.S. Patent No. 5,491,481 describes a method to form a corrosion resistant coating on a metal substrate including the steps of providing a homogenous powder mixture of a thermosetting resin and a solid, non-hydrolyzed, functional low molecular weight silane coupling agent, depositing a layer of powder mixture onto the substrate and heating the substrate to a temperature at least equal to the curing temperature for sufficient time to melt the resin and the silane. The resin is cured and forms a cross-linked layer that becomes tightly bonded to the substrate by the silane. This process is limited to the use of homogenous powder mixtures of an epoxy resin and silane and, furthermore, the process is limited to the use of silanes that are solids at ambient temperature. Liquid silanes have been found to polymerize too quickly.

- 8 -

Several years ago, the American Cyanamid Company developed and attempted to commercialize a water based emulsified epoxy primer, which contained an organosilane. W. D. Steinmetz and D. Kohli, "Water-
5 Based Primers for Aerospace Applications", published in "Proceedings of the 34th International SAMPE Symposium", Reno, NV (1989). However, this emulsified epoxy primer was inferior to the primer invention disclosed herein for at least the following reasons:
10 the emulsified primer did not work on non-PAA surfaces; it exhibited thickness sensitivity; and it had a short shelf life.

It is also known to provide corrosion protection
15 to steel sheet by coupling with a liquid resin containing a silane coupling agent. These liquid resins have the disadvantage that hydrolyzed silane solutions have a relatively short storage life. Organosilanol solutions tend to condense and polymerize
20 thereby minimizing their chemical interaction with paints. Thus, the hydrolyzed silanes have reduced effectiveness as coupling agents.

A comparative study of silanes as primers and
25 additives for epoxy adhesive resins has been conducted by E. D. Plueddeman in the article "Silane Primers for Epoxy Adhesives", *Journal of Adhesion Science Technology*, Vol. 2, No. 3, pp. 179-188, 1988. A
30 variety of silanes were applied to the surfaces of metal and glass substrates as a primer for an epoxy adhesive. After baking the silane an epoxy adhesive was added to the silane primer. The water resistance of epoxy bonds to the glass and metal was measured. Plueddeman found that silanes provided a more durable
35 bond; however, addition of the silane to the epoxy adhesive resin prior to curing instead of using the silane as a primer did not produce consistent results. In some cases the silane performed better as a primer

- 9 -

rather than an additive and in others the reverse was true. It appears that the ability of the silane to provide water-resistant bonds between epoxies and metals or glass depended in large part on the
5 particular silane employed.

More recently, corrosion protection to steel sheet was imparted by coating the sheet with a powder containing a silicone resin as described in U.S. Patent
10 No. 5,077,354. An in-situ polymeric binder mixture comprising an acrylic graft copolymer of a silicone resin in powder paint was employed. Silicone resin and ethylene monomers are dissolved in a solvent heated to 50°C to 150°C and mixed until polymerization is
15 completed. The solvent is stripped away leaving a non-gelled polymerization binder. A disadvantage of using this powder paint is believed to be that a good bond is not formed between the paint and steel substrate. Since the silicone resin had already reacted in-situ
20 when combined with the ethylenic monomers forming the acrylic powder, the silicone resin does not act as a coupling agent between the outer acrylic layer and the steel layer.

25 U.S. Patent No. 5,139,601 describes an improvement in the bonding of a metal substrate to a similar or dissimilar substrate wherein a primer coating is first applied to at least one metal substrate surface and then the similar or dissimilar
30 substrate is then bonded to the primer-coated metal substrate surface using a bonding adhesive. As at least part of the primer coating, a coating formed of a uniform, ultra-thin film made by immersing, prior to bonding said metal substrate, in a solution of at least
35 one hydrolyzable metal alkoxide of a polymeric network-forming cation, water, a solvent and a base, said solution having undergone substantially no polymer

- 10 -

growth, for a time sufficient to form in-situ said film on said substrate is utilized.

WO 97/17144 describes a method and composition
5 useful for treating metal surfaces prior to bonding of
the metal surfaces to other materials, including
metals, rubber, glass, polymers, sealants, coatings
and, in particular, polymeric adhesives to enhance
surface adhesion properties and prolong useful life in
10 corrosive environments. The composition comprises: (a)
water; (b) metal alkoxide comprising $M(OR)_x$, where M is
a metal and R is an alkyl group; (c) organoalkoxysilane
comprising silane coupling functional groups capable of
bonding with the material to be bonded to the metal
15 surface; and (d) acid to promote hydrolysis and cross-
linking of the metal alkoxide and organoalkoxysilane.

It would be an advance in the art to prepare an
aqueous adhesive primer which contains little or no
20 VOCs, which increases primary adhesion and is corrosion
resistant to environmental conditions when used with
commercial adhesives; which is storage stable for
extended periods of time when suitably stored (for
example, for a period in excess of 24 weeks when stored
25 at temperatures below 5°C, or for a period in excess of
three months at ambient temperature); which allows for
excellent adhesion of heat-curable resins to the metal
substrate, preferably similar to that of a freshly
cleaned metal surface; which can be easily and
30 economically prepared; and whose application to the
substrate is practical and economical.

SUMMARY OF THE INVENTION

35 The invention relates to a composition that is
useful as a primer for metal surfaces prior to bonding
to other materials, promotes corrosion resistance and
adhesion of metals, and prolongs useful life in

- 11 -

corrosive environments. The primer composition comprises: an aqueous dispersion of: (i) at least one thermosetting resin curable at an elevated temperature; (ii) at least one organosilane, each said organosilane
5 containing at least one hydrolyzable group; and (iii) a curing agent. The primer composition may be prepared by mixing the aforementioned components together. The thermosetting resin is preferably selected from the group consisting of epoxy, bismaleimide, phenolic and
10 unsaturated polyester resins.

In one preferred embodiment the primer composition comprises an aqueous dispersion of: (a) at least one epoxy resin curable at an elevated
15 temperature; (b) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (c) a curing agent.

The invention also relates to a bondable metal
20 structure comprising at least two metal surfaces bondable to one another at an interface, comprising: (a) a primer coating on each of the metal surfaces, each primer coating comprising an aqueous dispersion of: (i) at least one thermosetting resin curable at an
25 elevated temperature; (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (iii) a curing agent; and (2) a thermosetting adhesive between the primer coatings such that upon curing the primer coating is capable of
30 bonding with the metal surfaces and the thermosetting adhesive to form a strong and corrosion-resistant joint between the metal surfaces.

The invention further relates to a process for
35 adhering a first metal to a second adherend, comprising: (a) applying to said first metal a primer composition comprising an aqueous dispersion of: (i) at least one thermosetting resin curable at an elevated

- 12 -

temperature; (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (iii) a curing agent; (b) curing said primer composition to prime a surface of said first metal; (c) 5 applying a thermosetting adhesive between the primed surface of said first metal and said second adherend; and (d) applying heat and pressure sufficient to cure said thermosetting adhesive.

10 The invention also relates to a process for preparing a composite article comprising a metal article and a layer of crosslinkable resin bonded thereto comprising: (a) applying to said metal article a primer composition, comprising an aqueous dispersion 15 of: (i) at least one thermosetting resin curable at an elevated temperature; (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (iii) a curing agent; (b) curing said primer composition to form a primed metal 20 surface of said metal article; (c) applying a crosslinkable resin to said primed surface of said metal article; and (d) curing said crosslinkable resin.

The invention further relates to a process for 25 priming a metal surface comprising the steps of:

(a) coating the metal surface with a primer composition comprising an aqueous dispersion of: (i) at least one thermosetting resin curable at an elevated 30 temperature; (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (iii) a curing agent; and

(b) heating the primer composition to a 35 temperature sufficiently high to crosslink the primer composition to form an adherend coating on the metal surface.

- 13 -

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The primer composition and process of the present invention is useful for treating metal surfaces prior to bonding of the metal surfaces to other materials, including metals, rubber, glass, polymers, sealants, coatings and, in particular, polymeric adhesives to enhance surface adhesion properties and prolong useful life in corrosive environments. The primer composition of the present invention is particularly useful for promoting corrosion resistance and adhesion of metals, such as aluminum, steel, zinc, nickel, titanium, galvanized or plated metals and alloys. The primer composition is used in adhesively-bonded assemblies of metal to similar or dissimilar substrates whose adhesive bonds exhibit strong resistance to corrosion, heat, water, humidity and chemicals. The primer compositions of the present invention provide enhanced primary adhesion and corrosion protection at or under the bond line without the necessity for first pre-treating the metal surface for the bonding of metal to similar or dissimilar substrates. As employed herein the term "dispersion" means finely divided particles of a material in suspension in another substance. If desired, minor amounts of modified resin can be used in emulsified form in the present invention.

The primer composition of the present invention generally comprising an aqueous dispersion of: (i) at least one thermosetting resin curable at an elevated temperature; (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (iii) a curing agent.

The primer composition and the process for using the primer are illustrated herein by adhesive bonding of structural aluminum, the word "aluminum" includes high purity aluminum, commercial purity aluminum and

- 14 -

aluminum based alloys, such as, for example, the 2000 series (Al-Cu alloys) and the 7000 series (Al-Zn-Mg alloys). The primer composition and method can also be used in other applications, for example to promote: (i) paint adhesion, particularly if corrosion resistance is important as in air frames; (ii) polymer adhesion, for example thermosetting resins to metal surfaces, etc.; and (iii) adhesion of electroplated coatings.

10 The organosilane compound used in the primer composition has silane functional groups that can react or bond to the material to be bonded to a metal surface. Preferred organosilanes have the following formula:

15 wherein n is greater than or equal to 0; wherein each X is OH, OCH₃, and OCH₂H₅; wherein R₁ is CH=CH₂,

or CH₂-CH₂-CH₂-Y, wherein Y is NH₂, SH, OH, NCO,

20 NH-CO-NH₂, NH-(CH₂)₃NH₂, NH-Aryl,

, or

and wherein each R₂ is alkyl, alkoxy, aryl, substituted aryl, or R₁.

25

Examples of suitable commercial organosilane compounds available from OSi Specialties Inc., Danbury, CT include A-186, a beta-(3,4-epoxycyclo

- 15 -

hexyl)ethyltrimethoxy silane; A-187, a gamma-glycidoxypropyltrimethoxysilane; A-189, a gamma-mercaptopropyltrimethoxysilane; A-1100, a gamma-aminopropyltriethoxysilane; A-1106, an aminoalkyl
5 silicone solution; A-1170, a bis-(gamma-trimethoxy-silylpropyl)amine; Y-9669, a N-phenyl-gamma-aminopropyl-trimethoxysilane; Y-11777, an amino alkyl silicone/water solution; and Y-11870, an epoxy functional silane solution. Other suitable
10 commercially available organosilanes include Z-6040, a gamma-glycidoxypropyltrimethoxy silane from Dow Corning, Midland, MI and HS2759, an aqueous epoxy functional silane; HS2775, an aqueous amino silane solution; and HS2781 an aqueous oligomeric silane
15 solution with amino and vinyl groups all sold by Huls America Inc., Somerset, N.J. Generally the organosilanes are present in the primer composition in amounts from about 0.01 to 75 parts per hundred parts of the thermosetting resin, preferably from about 0.01
20 to 30 parts per hundred parts of the thermosetting resin, more preferably from about 0.01 to 10 parts per hundred parts of the thermosetting resin and most preferably from about 1 to 7 parts per hundred parts of the thermosetting resin.

25

Preferably, the liquid organosilanes are added directly to the aqueous primer composition. The organosilanes are then dispersed in water using conventional methods. For example, one method of
30 dispersing the organosilanes in water comprises dripping the organosilanes into an aqueous solution of thermosetting resin under vigorous stirring. The organosilanes can also be initially dissolved or suspended in a solvent that is miscible with water. In
35 the latter case, the organosilane solution is simply added to the water, without excessive stirring or mixing. The aqueous organosilane solution is then mixed with an aqueous thermosetting composition.

- 16 -

The thermosetting resins that are most useful in the subject invention are epoxy, bismaleimide, phenolic and unsaturated polyester resins. Particularly preferred resins are epoxies and bismaleimides. The epoxy resins of the subject invention are conventional solid epoxy resins having functionalities, of at least about 1.8, preferably at least about 2 functionalities and containing substantially no ionic or ester groups, as described in *Epoxy Resins*, Lee and Neville, McGraw-Hill, Chapters 1 to 4. Preferred epoxy resins are the optionally chain-extended, solid glycidyl ethers of phenols, such as resorcinol and the bisphenols, e.g. bisphenol A, bisphenol F, and the like. Also suitable are the solid glycidyl derivatives of aromatic amines and aminophenols, such as N,N,N',N'-tetraglycidyl-4,4'-diaminodiphenylmethane. Preferred are the solid novolac epoxy resins and solid diglycidyl ether of bisphenol A ("DGEBA") resins. The epoxy resins must be in a solid form, or produce a solid composition when admixed with other epoxies.

Examples of suitable commercial epoxy resins are Epi-Rez® SU-8, a polymeric epoxy resin with an average functionality of about 8, melting point (Durrans) of 82°C, and an epoxy equivalent weight of 215 available from Shell Chemical Co.; DER 669, a high molecular weight solid epoxy resin having a Durrans softening point of 135°C to 155°C and an epoxy equivalent weight of 3500-5500 available from the Dow Chemical Company; Epi-Rez® 522-C, a solid DGEBA epoxy having an epoxy equivalent weight of 550-650 and a Durrans melting point of 75°C to 85°C, available from Shell Chemical Co.; and ECN 1273, 1280, and 1299 novolac solid epoxy resins having epoxy functionalities from 3.8 to 5.4, epoxy equivalent weights of from 225 to 235, and melting points of from 73°C to 99°C, available from Ciba-Geigy. These resins are generally supplied in solid form and ground to the correct particle size, or

- 17 -

supplied as an aqueous dispersion. For example, ECN-1299 is available as an aqueous dispersion from Ciba-Geigy as ECN-1440, and Epi-Rez® 522C is available from Shell Chemical Co. as 35201 epoxy dispersion.

5

Bismaleimide resins are also well known to those skilled in the art. Preferred bismaleimides are derived from toluenediamine, methylenedianiline, aliphatic diamines, isophorone diamine, and the like.

10 Bismaleimide monomers are well known to those skilled in the art, and are generally prepared by the reaction of maleic anhydride, or substituted maleic anhydride, with a suitable diamine. Both aromatic and aliphatic diamines are suitable for the preparation of the

15 bismaleimide. Suitable diamines for the preparation of bismaleimides also include other aromatic diamines such as phenylenediamine, diaminodiphenylsulfones, diaminodiphenylisopropylidenes, diaminodiphenylketones, diaminodiphenyloxides and diaminodiphenylsulfides.

20 Bismaleimides derived from diamines containing heteroatoms are also useful.

Generally, the bismaleimides are copolymerized with an alkenylphenol or an alkenyloxyphenyl comonomer.

25 Suitable alkenylphenols are o,o'-diallyl- and o,o'-dipropenylbisphenol A, bisphenol F and/or bisphenol S. Also suitable are alkenylphenol and alkenyloxyphenyl terminated dicyclopentadienes.

30 The bismaleimide resin system of the subject invention may contain one or more comonomers. These comonomers may be comonomers which react with the bismaleimide monomers, or which react with themselves or with other comonomers or may be the same or a

35 different bismaleimide resin in liquid form. Such comonomers include, for example, those described in U.S. Patent Nos. 4,100,140 and 4,035,345, which are incorporated herein by reference. In addition to such

- 18 -

comonomers, the resin systems of the subject invention may also include engineering thermoplastic tougheners, particularly polyimides, polyetherimides, polyetherketones, polyarylenesulfides, 5 polyarylenesulfones, polyethersulfones, and the like. Such thermoplastic tougheners should have glass transition temperatures, T_g , in excess of about 100°C.

Suitable epoxy comonomer resins are disclosed in 10 the treatise Handbook of Epoxy Resins, McGraw-Hill, Inc., 1967. Examples of such resins are the bisglycidyl ethers of the bisphenols, particularly bisphenol A, bisphenol F and bisphenol S. Also suitable are the various phenolic and cresolic 15 novolac-type resins, as well as the venous glycidoxy amines and aminophenols, particularly N,N,N', N'-tetrakis(glycidyl)-4,4-diaminodiphenyl methane and N,N,O-tris(glycidyl)-4-aminophenol. Epoxy resins based on the glycidyl ethers of the various dihydroxy- 20 naphthalenes and phenolated dicyclopentadienes are also suitable.

The phenolic resin can comprise novolac type phenolic resin (the so-called random novolac type 25 phenolic resin) wherein the ratio of o-methylene to p-methylene bond is less than 1.0 and/or a resole type phenolic resin (methylol type, or dimethylene ether type). Mixtures of the ordinary novolac type phenolic resin and/or the resole type phenolic resin may also be 30 used.

Thermoplastic phenoxy resins are suitable for use as modifiers and tougheners in the present invention. These are of the waterborne type, preferably those prepared according to the general procedures described 35 in U.S. Pat. Nos. 4,355,122, and 4,638,038, the disclosures of which are incorporated herein by reference.

- 19 -

Water soluble polyether polymers suitable for use as modifiers herein include at least one of a poly(ethylene oxide) or a poly(vinylmethylether) polymer. The poly(ethylene oxide) polymers are well
5 known and commercially available. They are prepared by methods well known in the art and as found in, for example, U.S. Pat. No. 3,417,064.

Emulsions of thermosetting resins, for example
10 emulsified epoxies, may be used as coreactants or modifiers in the present invention. These emulsions may be added to the compositions of the present invention at 1% to 10% levels. Suitable emulsified epoxies are commercially available from Shell Chemical
15 Co., Ciba-Geigy and Vianova. Some examples include ER 3510-W-60 and ER 3515-W-60 from Shell Chemical Co. or PY 323 from Ciba-Geigy.

The aqueous dispersion of the present invention
20 includes a dispersed phase in amounts from 60 to about 10 percent by weight of said aqueous dispersion, and an aqueous continuous phase in amounts from 40 to about 90 percent by weight of said aqueous dispersion. The dispersed phase may preferably comprise a dispersion of
25 more than one thermosetting resin as a mixture of distinct particles, or may consist of only one type of particle containing more than one thermosetting resin. For example, a flexibilizing epoxy such as a higher molecular weight bisphenol A or a bisphenol F epoxy may
30 be blended with a highly temperature resistant epoxy such as tetraglycidyl ether of methylene dianiline ("TGMDA") and the mixture cooled, ground, or otherwise dispersed into solid particles of the requisite size. These same epoxy resins may be advantageously dispersed
35 separately without blending.

As indicated above, a preferred epoxy mixture comprises a solid epoxy resin having an epoxy

- 20 -

functionality of no greater than 5.5, and a solid epoxy resin having a functionality of at least 6. The use of higher functionality epoxy resins, i.e. epoxy resins having at least five epoxy functionalities, in minor amounts is preferred. In general less than 40 weight percent of such higher functionality epoxy resins is used based on the sum of the weights of all epoxy resins in the composition. The use of such higher functionality epoxy resins in such minor amounts has been unexpectedly found to increase the solvent resistance of the cured primer without lowering adhesive properties substantially. A preferred high functionality epoxy resin is Epi-Rez® SU-8, a polymeric solid epoxy resin having an average of eight epoxy functionalities.

An especially preferred epoxy composition is a mixture of:

- (i) from about 30 to about 70 weight percent of a solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of from about 400 to about 800;
 - (ii) from about 5 to about 20 weight percent of a solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of from about 2000 to about 8000;
 - (iii) from about 5 to about 40 weight percent of a solid epoxy resin having an epoxy functionality of at least 5 and having an epoxy equivalent weight of from about 100 to about 400; and
- said weight percents of said (i) to (iii) totaling 100 percent based on total weight of the epoxy component.

- 21 -

Also especially preferred is a mixture of:

(i) from about 30 to about 70 weight percent of a solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of
5 from about 400 to about 800;

(ii) from about 5 to about 20 weight percent of a solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of
10 from about 2000 to about 8000;

(iii) from about 5 to about 40 weight percent of a solid epoxy resin having an epoxy functionality of at least 5 and having an epoxy equivalent weight of from
15 about 100 to about 400; and

said weight percents of said (i) to (iii) totaling 100 percent based on total weight of the epoxy component.

20

The invention also provides for a bondable metal structure comprising at least two metal surfaces bondable to one another at an interface, comprising:

25 (1) a primer coating on each of the metal surfaces, each primer coating comprising an aqueous dispersion of: (a) one or more thermosetting resins curable at an elevated temperature; (b) one or more organosilanes, each organosilane containing at least
30 one hydrolyzable group; and (c) a curing agent; and

(2) a thermosetting adhesive between the primer coatings such that upon curing the primer coating is capable of bonding with the metal surfaces and the
35 thermosetting adhesive to form a strong and corrosion-resistant joint between the metal surfaces.

- 22 -

A process is provided for adhering a first metal to a second adherend, comprising:

- (1) applying to said first metal a primer
5 composition, comprising an aqueous dispersion of:
(a) one or more thermosetting resins curable at an elevated temperature; (b) one or more organosilanes, each organosilane containing at least one hydrolyzable group; and (c) a curing agent;
10
- (2) curing said primer composition to prime a surface of said first metal;
- (3) applying a thermosetting adhesive between the
15 primed surface of said first metal and said second adherend; and
- (4) applying heat and pressure sufficient to cure said thermosetting adhesive.
20

A process for preparing a composite article is also provided comprising a metal article to which is bonded a layer of crosslinkable resin comprising:

- (1) applying to said metal article which is to be
25 bonded to said crosslinkable resin a primer composition, comprising an aqueous dispersion of: (a) one or more thermosetting resins curable at an elevated temperature; (b) one or more organosilanes, each
30 organosilane containing at least one hydrolyzable group; and (c) a curing agent;
- (2) curing said primer composition to form a primed metal surface of said metal article;
35
- (3) applying a crosslinkable resin to said primed surface of said metal article; and

- 23 -

(4) curing said crosslinkable resin.

Preferably the primer is applied to the first metal or the metal article in an amount such that when
5 cured, preferably a primer coating of from about 0.0001 inch to about 0.005 inch thickness is obtained, more preferably a primer coating of from about 0.0001 inch to about 0.0005 inch thickness is obtained and most preferably a primer coating of from about 0.00015 inch
10 to about 0.0003 inch thickness is obtained. The crosslinkable resin is a thermosetting resin which may be applied in any workable form such as a sheet, a liquid or a paste. Typical liquids include paint and the like. The thermosetting resin may further
15 incorporate fibrous reinforcement.

A process for priming a metal surface prior to bonding the metal surface is also provided with the process comprising the steps of:

20

(1) coating the metal surface with a primer composition comprising an aqueous dispersion of: (a) one or more thermosetting resins curable at an elevated temperature; (b) one or more organosilanes, each
25 organosilane containing at least one hydrolyzable group; and (c) a curing agent; and

(2) heating the primer composition to a temperature sufficiently high to crosslink the primer
30 composition to form an adherend coating on the metal surface.

The process for priming a metal surface prior to bonding the metal surface may further comprise the step
35 of roughening the metal surface prior to coating the metal surface with the primer composition. The roughening may be conducted by acid etching or abrading the metal surface.

- 24 -

- The curing agents of the subject invention are preferably substantially water insoluble, and solid at room temperature. Examples of such curing agents are aromatic amine curing agents such as 4,4'-
- 5 diaminodiphenylmethane, 2,2-bis(4-[4-aminophenoxy]phenyl)propane, 3,3'- and 4,4'-diaminodiphenylsulfone, 3,3'- and 4,4'-diaminodiphenyloxide, 3,3'- and 4,4'-diaminodiphenyloxide, 3,3'- and 4,4'-
- 10 diaminodiphenylsulfide, and 3,3'- and 4,4'-diaminodiphenylketone. Other suitable solid diamine curing agents include 2,4-toluenediamine, 1,4-phenylenediamine, 2,2-bis(4-aminophenyl)hexafluoropropane, 2,2-bis(3-amino-4-hydroxyphenyl)hexafluoro
- 15 propane, 3,4'-diaminodiphenyloxide, 9,9-bis(4-aminophenyl)fluorene, o-toluidine sulfone, and 4,4'-diaminobenzanilide. Particularly preferred are 9,10-bis(4-aminophenyl)anthracene, 2,2-bis(4-[3-aminophenoxy]phenyl)sulfone, 2,2-bis(4-[4-
- 20 aminophenoxy]phenyl)sulfone, 1,4-bis(4-aminophenoxy)biphenyl, bis(4-[4-aminophenoxy]phenyl) ether, and 2,2-bis([4-(4-amino-2-trifluorophenoxy)]phenyl)hexafluoropropane. Also preferred is XU 95101 a curing agent commercially available from Ciba-Geigy.
- 25 Most preferably, those solid amine curing agents having melting points below 240°C, preferably below 175°C are utilized. Most preferred as a curing agent is 4,4'-[1,4-phenylene(1-methylethylidene)]-bis(benzeneamine).
- 30 Also suitable are the amino and hydroxyl terminated polyarylene oligomers wherein the repeating phenyl groups are separated by ether, sulfide, carbonyl, sulfone, carbonate, or like groups. Examples of such curing agents are the amino-and hydroxyl-
- 35 terminated polyarylenesulfones, polyarylene-ethersulfones, polyetherketones, polyether-etherketones, and like variants. The curing agents are

- 25 -

usually present in amounts from about 2 to about 30 parts per hundred of said thermosetting resin.

A primer composition is provided which comprises
5 an aqueous dispersion of

(A) (a) a dispersed phase from about 60 to about 10 percent by weight of said aqueous dispersion and (b) an aqueous continuous phase from about 40 to about 90
10 percent by weight of said aqueous dispersion, and wherein an epoxy resin is present as a mixture of epoxy resins comprising:

(i) from about 30 to about 70 weight percent of a
15 solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of from about 400 to about 800;

(ii) from about 5 to about 20 weight percent of a
20 solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of from about 2000 to about 8000;

(iii) from about 5 to about 40 weight percent of
25 a solid epoxy resin having an epoxy functionality of at least 5 and having an epoxy equivalent weight of from about 100 to about 400; and

said weight percents of said (i) to (iii)
30 totaling 100 percent based on total weight of the epoxy component;

(B) at least one organosilane, each said organosilane containing at least one hydrolyzable
35 group, said organosilane is selected from the group consisting of beta-(3,4-epoxycyclohexyl) ethyl trimethoxysilane, gamma-glycidoxypropyl trimethoxy silane, gamma-mercapto propyltrimethoxy silane,

- 26 -

gamma-aminopropyltriethoxy silane, bis-(gamma-trimethoxy silylpropyl)amine, N-phenyl-gamma-aminopropyltrimethoxy silane, and (3-glycidoxypropyl) methyldiethoxysilane; and

5

(C) an aromatic curing agent selected from the group consisting of 2,2-bis(4-[4-aminophenoxy]-phenyl)propane, 4,4'-diaminodiphenylsulfone, 3,3'-diaminodiphenylsulfone, 4,4'-diaminodiphenyl ketone, and 4,4'-[1,4-phenylene(1-methylethylidene)]bis (benzeneamine).

10

Catalysts are generally unnecessary; however, solid, water-dispersible catalysts may be added when the particular curing agent is not sufficiently active at the primer composition bake temperature to effect cure of the primer composition. The catalyst may be water soluble, water insoluble, or in particulate form having a particle size such that essentially 100 percent of the particles have mean diameters less than about 30 μm . Typical catalysts that may be employed, include but are not limited to the following, bisureas, blocked imidazoles, substituted imidazoles or other blocked amines such as amine/epoxy adducts, hydrazines, etc.

20

25

Preferred catalysts have the following formula:

wherein R_3 and R_4 are independently selected from the group consisting of aryl, substituted aryl, biphenyl, naphthyl and cycloaliphatic and Z may be selected from the group consisting of alkyl, O, S, and SO_2 ; wherein p is 0 or 1; and q is an integer from 1 to 3.

30

- 27 -

Particularly preferred catalysts are represented by the following formulae:

5

DIURON®; and

MONOURON®.

10 MONOURON® and DIURON® are commercially available from Du-Pont Chemical Co.

- 28 -

Volatile organic solvents are generally undesirable and unnecessary. However, if need be minor amounts of such a solvent, i.e. less than 1-5% by weight, can be employed. Examples of volatile organic solvents which could be added without significantly affecting the function and physical properties of the composition include low molecular weight glycols and glycol ethers, N-methylpyrrolidone, and similar solvents. By the term "substantially solvent free of volatile organic solvents" as employed herein is meant that the system contains no volatile organic solvent or such a minor amount that substantially no advantage or difference can be ascertained between the cured physical properties obtained from the completely solventless system and the system containing the minor amount of solvent.

The compositions of the subject invention may include tougheners useful in adhesive systems, for example elastomers, preferably reactive elastomers such as those containing carboxyl, epoxy, amino, or hydroxyl functionalities. If the elastomer is a liquid elastomer, such as a liquid rubber sold under the trade name HYCAR, then the elastomer must first be reacted with an epoxy resin, either a solid or liquid epoxy, to form a prereact chain-extended elastomer which is a solid. The solid prereact may then be ground or milled to particle sizes less than 30 μm , preferably less than 20 μm , and most preferably such that the majority of particles are in the 2-5 μm range or below. If the elastomer is solid, then it may be ground by cryogenic means or the like, if not supplied in the appropriate size range. Whether formed as a prereact or already in solid form, the elastomer is then dispersed with the remaining ingredients.

The amounts of added elastomer are not critical, and amounts from 1 to about 30 weight percent,

- 29 -

preferably from about 5 to about 15 weight percent, based on total primer solids are generally adequate.

The composition may optionally contain

5 conventional dyes, pigments, fillers, leveling agents, additional dispersing agents, thickeners, corrosion inhibitors and the like. A benefit of compositions containing dyes or pigments is that surface coverage can be assessed more easily by visual methods. The

10 corrosion inhibitor may be a chromate or a non-chromate inhibitor. Examples of suitable chromate corrosion inhibitors include strontium chromate, barium chromate, zinc chromate, and calcium chromate. Suitable amounts of the chromate corrosion inhibitors range from about

15 0.125 weight percent to about 30 weight percent. In the case of the presence of fillers in the composition, particularly preferred is fumed colloidal silica.

Non-chromate corrosion inhibitors can also be

20 used in the composition of the present invention. Preferred examples of non-chromate corrosion inhibitors are zinc phosphate, zinc molybdate and SICORIN RZ available from BASF AG, Ludwigshafen, Germany. Suitable amounts of the non-chromate inhibitors range

25 from about 0.125 weight percent to about 15 weight percent.

The dispersions are generally prepared by first dispersing the solid thermosetting resin(s) or blend of

30 solid thermosetting resins into an aqueous vehicle. The thermosetting resins may be heated to above their melting point or dissolved in a solvent to form a concentrated solution, the solvent being later removed by distillation or stripping. Preferably, no solvent

35 is utilized. The resultant liquid thermosetting resin or thermosetting resin solution is dispersed into water to provide solid fine particles by slow addition under high shear agitation; by forcing the thermosetting

- 30 -

through metal plates containing numerous micron-sized holes into rapidly agitated water; or by like methods well-known to those of ordinary skill in the art.

5 Finely ground solid thermosetting resins may be utilized instead of molten, normally solid thermosetting resins. To aid in the maintenance of a stable dispersion, an effective amount of a surfactant may be added. Such a surfactant preferably contains
10 both hydrophilic and hydrophobic (lipophilic) portions. Typically surfactants include simple soaps such as the sodium and ammonium salts of long chain fatty acids, long chain fatty alcohol ethoxylates, alkylphenol ethoxylates or block polyoxyalkylene polyethers
15 containing a hydrophobic moiety derived from repeating polyoxypropylene or polyoxybutylene groups or one or more long chain olefin oxide reaction products and a hydrophilic group comprising repeating oxyethylene groups.

20

To avoid the necessity of dispersing the thermosetting resins, commercially available dispersions may be utilized to supply certain of the thermosetting resin ingredients. In the case of epoxy
25 dispersions a number are available from commercial sources, for example from Ciba-Geigy, ECN-1400, a dispersion of epoxy novolac ECN 1299 in water; and Epi-Rez® 35201, a dispersion of a solid DGEBA epoxy resin, CMD W50-3519, an elastomer modified epoxy dispersion,
30 and W55-5003, an SU-3 epoxy dispersion, all available from Shell Chemical Co.

The particle size of the thermosetting resin should be such that essentially 100 percent of the
35 particles have sizes less than 30 μm , preferably less than 20 μm . Best results are obtained with essentially 100 percent of the particles being less than 16 μm , with 90 percent less than 2 μm . Such particles sizes

- 31 -

may be obtained by the methods previously described, or by traditional grinding methods such as jet milling, ball milling, or media milling such as zirconium oxide or sand milling. In general, the finer the particle size, the more dispersible the thermosetting resin will be, and also the more resistant to sedimentation. In addition, small particle sizes have been unexpectedly found to increase solvent resistance of the cured primer. The particle sizes herein are measured with a Brinkmann Particle Size Analyzer based on probability number density.

Following dispersion of the thermosetting resin(s) into the aqueous phase, the curing agent is added. The curing agent is first reduced to a fine particle size, preferably from about 0.1 μm to about 30 μm , and more preferably from about 1 μm to about 10 μm , in diameter, whereby essentially 100 percent of the particles have mean diameters less than 30 μm .

The curing agent may be also reduced to small particle size by known methods, including spray drying, solution precipitation, ball milling, sand milling, air jet milling, and the like. The fine curing agent particles are added to the thermosetting emulsion or dispersion and agitated until a uniform mixture is obtained. Following or preceding addition of the curing agent, other additives such as dyes, pigments, corrosion preventatives, and the like, may be added.

Either following or before dispersion of the curing agent into the aqueous phase, one or more organosilanes are added. Liquid organosilanes may be added alone or first dissolved in a solvent. Suitable solvents include any solvent miscible with water, and more preferably miscible with one or more of the added thermosetting resins, and such solvents include alcohols, such as methanol, ethanol and isopropanol.

- 32 -

Solid organosilanes may be added in powder form directly to the aqueous dispersion of the thermosetting resins and/or curing agent or alternatively, they may be first placed in a solvent such as the type listed
5 for the liquid organosilanes. The primer composition thus prepared forms a stable liquid solution or dispersion useful for coating a metal surface.

Preferably, the aqueous vehicle is water, more
10 preferably distilled or deionized water. Optionally, the composition can also include conventional solvents useful for dissolving and dispersing organic compounds. Both the water and solvent at least partially hydrolyze the one or more organosilanes of the primer
15 composition. Suitable conventional solvents include any solvent miscible with water, and more preferably miscible, with the one or more thermosetting resins and the one or more organosilanes. Such solvents include alcohols, such as methanol, ethanol and isopropanol.
20

With regard to the amine curing agent-thermosetting resin ratios, the amine to thermosetting stoichiometry may range from about 0.5 to about 1.5. However, if maximum solvent resistance is desired, the
25 amine/thermosetting ratio should be from about 0.8 to about 1.5, preferably about 1.0. Solvent resistance is assessed by wiping with methylethylketone solvent twenty times after the primer is cured. Acceptable solvent resistance is shown when following 20 wipes
30 there is negligible visible damage to the film, i.e. the film is still intact and of substantially the same thickness as initially. There should be little or no loss of polymer from the cured film.

35 The low VOC primer is applied by traditional methods, for example by air driven or airless spray guns, by high volume low pressure spray guns, and the like, such as for example, a Binks Model 66 spray gun.

- 33 -

Following drying, the finish is baked at a temperature sufficient to cure the coating. Nominal curing temperatures range from about 60°C to about 200°C, preferably from about 100°C to about 180°C, and most preferably from about 115°C to about 125°C. Cure time is dependent upon cure temperature and can be, for example from about 0.5 to about 4 hours. Preferably, the primer is cured at about 120°C for one hour. Nominal cured coating thickness is from about 0.02 to about 1.0 mils (0.5 to 25.4 μm), preferably from about 0.05 to about 0.5 mils (1.3 to 12.7 μm), and especially from about 0.05 to about 0.25 mils (1.3 to 6.4 μm).

Surprisingly, even though the thermosetting resin and curing agent are in generally distinct phases, the coatings produced are of exceptionally high quality. The resultant adherend coating contains functional groups that enhance adhesion of the metal surface by coupling or polymerizing with the material to be bonded to the metal surface, and, in particular, with the polymeric adhesive used to bond metal surfaces to one another. Another advantage of the present composition is that tailored coating microstructures with the desired pore sizes, volume, distribution and lengths can be formed in the adherend coating to provide a tortuous pore structure that provides enhanced bonding capability.

Also, the adherend coating typically resists hydration by diffused moisture and protects the underlying metal surface from corrosion. In addition, the composition is environmentally benign and can be used to coat large areas for mass production, at low cost, and without the use of toxic chemicals, and without use of large amounts of electrical power. In this manner, the composition of the present invention provides an unusually durable and corrosion resistant coating.

- 34 -

An exemplary adhesive-bonded joint formed between two or more metal surfaces using the primer composition of the present invention will now be described. A typical adhesive-bonded joint between metal surfaces
5 comprises (i) adherend coatings of the primer composition of the present invention on the metal surfaces; and (ii) a polymeric adhesive, such as an epoxy, for bonding the primed metal surfaces to one another.

10

Once the primer has been applied to a first substrate, such as a metal surface, a second adherend, such as a second metal substrate or a composite substrate, can be adhered to the so-primed first
15 substrate in a normal manner by positioning a thermosetting adhesive between the primed surface of the substrate and the second adherend, then applying heat and pressure sufficient to cure thermosetting adhesive. Suitable thermosetting adhesives include
20 FM®73, FM®94, FM®300 and FM®377 adhesive films commercially available from Cytec Engineered Materials, Havre de Grace, MD. FM®73 is a toughened general purpose epoxy adhesive film designed for continuous service at 82°C. FM®94 is an improved version of
25 FM®73. FM®377 is a 177°C service adhesive with good toughness. Additional thermosetting adhesives suitable for a particularly application, as well as the suitability for such application and curing conditions thereof, are well-known to those of ordinary skill in
30 the art. These include epoxies, polyester, epoxy-polyester, bismaleimide, acrylic, cyanate ester, acrylic-urethane or fluorovinyl thermosetting adhesives.

The following examples demonstrate the
35 suitability of the composition and method for coating and bonding a number of metal surfaces, including AM355 steel, 2024-T3 aluminum, bare- and alclad-aluminum and 6AL-4V titanium. The surface preparation for steel

- 35 -

substrates involved either an acid etch or grit blasting followed by a final solvent wipe. The aluminum skins were prepared by one of three different methods: (1) grit blasting followed by a solvent wipe; 5 (2) Forest Products Laboratories etch ("FPL"); and FPL followed by phosphoric acid anodization according to the American Standard Testing Method ("ASTM") 3933 protocol. The titanium substrates were prepared by 10 grit blasting and solvent wiping.

10 The following examples also detail the preparation of primer formulations with and without a silane adhesion promotor. The primers of the present invention were sprayed onto the cleaned surface of a 15 metal panel for testing, the primer coated metal material was allowed to stand at room temperature for 30 minutes, which was then followed by drying at 121°C for one hour. The target thickness for the primer on the surface of the metal panel was typically from about 20 0.20 to about 0.30 mils, although other thicknesses were also found to provide satisfactory results.

A polymeric adhesive, such as an epoxy adhesive was applied to the coated metal surfaces for bonding 25 the metal surfaces to one another. After application of the polymeric adhesive to the coated metal surfaces, the metal surfaces are joined to one another, and the joint is firmly held during heat treatment at a temperature and pressure suitable for curing and 30 bonding the metal surfaces to one another. For example, for the FM®73 film adhesive, a suitable heat treatment is at a temperature of from about 120°C for about 60 minutes, under an applied pressure of about 40 psi. In the case of FM®377 adhesive a cure cycle of 90 35 minute heat up to 177°C followed by a 120 minute hold at 177°C, under an applied pressure of about 40 psi was used. While with FM®94 and FM®73 adhesives the cure cycle consisted of a 60 minute heat up to 121°C

- 36 -

followed by a 90 minute hold at 121°C, under an applied pressure of 40 psi.

5 Metal surfaces joined using the composition and
process of the present invention have high shear
strengths and good corrosion resistance in harsh
environments. The shear strength of a metal joint
fabricated using a water based composition of the
present invention, as measured by the lap shear joint
10 test described in ASTM D 1002, are typically above
those obtained when the metal surface is treated using
current commercially available primers. Also, the
coatings exhibited good thermodynamic and hydrolytic
stability as well as corrosion resistance. Additional
15 mechanical tests were performed on some of metal
surfaces joined using the compositions of the present
invention included climbing drum peels according to
ASTM D 1781 and floating roller peels according to ASTM
D 3167.

20 The environmental stability of the joints formed
using the process of the present invention were tested
using a wedge crack test according to ASTM 3762-79.
Within the tested range, the coatings yielded
25 substantially equivalent, and in many cases less crack
growth than that obtained from phosphoric anodizing
processes, which indicates good environmental
stability.

30 The following examples demonstrate the
suitability of the composition and method for coating
and bonding aluminum, steel and titanium substrates.

35 EXAMPLES 1-3
PRIMER PREPARATION

- 37 -

Primers were prepared having the following compositions by dispersing the following ingredients, in parts by weight.

	COMPONENT	Example 1 (weight percent)	Example 2 (weight percent)	Example 3 (weight percent)
5	Epi-Rez® SU-8 epoxy resin ^{1/}	10.6	10.0	10.6
	DER 669 epoxy resin ^{2/}	13.5	0	13.5
10	Bisphenol A/epichlorohydrin copolymer dispersed in water (XU 3903) ^{3/}	45.5	47.4	45.5
15	Elastomer modified Bis A epoxy dispersed in water (EPI-REZ® 3519-W-50 Waterborne Resin) ^{4/}	0	10.3	0
20	2,2-Bis-4-(4-aminophenoxy)phenyl propane	10.2	12.3	10.2
	Toluene-2,4-bis-(N,N'-dimethyl urea)	3.0	3.0	3.0
	Fumed Silica	1.8	1.8	1.8
25	Yellow Dye	0.3	0.3	0.3
	Strontium Chromate	15	12	0
	Water	To provide 20 percent solids content	To provide 20 percent solids content	To provide 20 percent solids content

- 1/ Product of Shell Chemical Co., a solid epoxy resin having a functionality of c.a. 8, and an epoxy equivalent weight ("EEW") of 215.
- 2/ Product of Dow Chemical Co., a diphenol A based solid epoxy having an EEW of 2300-3800 and a softening point of from 135-155°C.
- 35 3/ Product of Ciba-Geigy, a water dispersion of a solid bisphenol A epoxy resin having a viscosity of 12000 cps at 25°C and 80 percent solids.
- 4/ Product of Shell Chemical Co., a nonionic aqueous dispersion of an elastomer modified bisphenol A

- 38 -

based epoxy resin, having a viscosity of 13000 cps at 25°C and weight per epoxide of 600.

EXAMPLE 4

5

Primer formulations containing silane were prepared by adding, using a plastic pipet, 1-part Z-6040 (glycidoxypopyl trimethoxysilane available from Dow Corning) per 100 parts of each of the primer formulations prepared in Examples 1-3. These silane containing primer formulations were identified as (4-1) for Example 1, (4-2) for Example 2, and (4-3) for Example 3. Once the addition of the silane was completed, the resulting mixture was shaken to disperse the silane. Before use the primer formulation containing silane was again shaken.

EXAMPLE 5

20 The primer formulation (4-1) from Example 4 was used to prime 2024 T3 aluminum adherends. The following tables indicate that the primer (4-1) performed its function well, promoting bonding between adherends with the aid of structural adhesives which provide improved hot/wet properties compared to the unmodified primers. The adhesive film used to bond the two aluminum adherends was FM377 a 177°F service adhesive with good toughness. The 1/2" lap shear was measured by the lap shear joint test according to ASTM D 1002 and measures shear strength of the adhesive joint. The higher the lap shear strength the stronger the bond formed between the two surfaces being bonded together. The climbing drum peels according to ASTM D 1781 and floating roller peels according to ASTM D 3167 were carried out to measure the toughness of the bonded joint and film adhesive. The higher the climbing drum peel value the tougher the film. The wedge crack test according to ASTM 3762-79 was conducted and measures the durability of the bonded joint. The lower the

- 39 -

value for the crack length after 28 days of testing under hostile conditions the more durable the bond and less crack growth will be observed.

5 The results shown in Tables 1 and 2 demonstrate that the primer containing silane when used on a poorly prepared grit blasted aluminum surface significantly improves the bond strength and film toughness on the aluminum substrates. When the aluminum was exposed to
10 hostile environmental conditions such as 30 days at 60°C with 100% relative humidity the lap shear strength for the aluminum surface having a primer containing silane improved by 75% compared to the control sample.

15 The higher the value for the climbing drum peel test the tougher the adhesive film. The results of the climbing drum peel test in Table 2 showed that the primer with silane applied to a grit blasted aluminum surface tested in a highly corrosive environment (30
20 days with 5% salt spray) outperformed a control sample by over 200%. Furthermore, the primer with silane also performed better than a control which was applied to a surface that had first been treated with PAA. Thus the primers of the present invention can be used on even
25 poorly prepared surfaces, i.e., grit blast, and still provide the desired strength in the bonded joint.

The following table shows the wedge test results for aluminum substrates bonded together with FM®377 in the presence of a primer either with or without silane

30 adhesion promoter present. Each of the resulting aluminum structures were exposed to 60°C with 100% relative humidity during testing. The crack growth results in Table 3 clearly demonstrate that the aluminum structure with a primer containing silane is

35 more durable compared to a structure fabricated from control material. After four weeks the structure having grit blasted aluminum with primer containing silane (4-1) had a crack length of 1.60 inches while the control structure had a crack length of 2.57

40 inches, almost a full inch more. Furthermore, the crack length results for the structure with primer (4-1) compared very well to the results obtained for control structure whose surface was first prepared with PAA treatment. The primers of the present invention

- 41 -

significantly improve the durability of the bonded structure.

Crack extension studies showed similar results to those obtained for the crack wedge tests shown in Table 3. The following table shows the crack extension tests results following exposure of a number of aluminum structures to 60°C with 100% relative humidity during testing. The performance of the silane containing primer (4-1) on both grit blasted aluminum and FPL aluminum surfaces provide comparable results to those obtained for aluminum surfaces prepared using PAA treatment.

EXAMPLE 10

FM®94 adhesive was tested with the primer compositions containing silane of the present invention on acid etched steel surfaces. In addition, commercially available solvent-based primers BR127 Cytec Materials Inc., Havre de Grace, MD and EA9210B Hysol, Pittsburgh, CA were tested and compared to the primers of the present invention. The solvent based primers were found not to perform as well as the aqueous primer containing silane from Example 4 as shown by the results in the following tables. It was also found that when the steel surface was first treated with Z-6040 followed by spraying with the primer from Example 1 the resulting shear strengths were not as good as those obtained by spraying the surface with aqueous primer (4-1) from Example 4 which contained the silane adhesion promoter Z-6040. Thus, the primers of the present invention have the best resistance to heat and humidity compared to even the traditional solvent-based primers on steel, i.e., BR127. Furthermore, in wedge crack tests (Table 14) it was found that grit blasted aluminum surfaces with primer containing silane (4-1) maintained the shortest crack length over a four week period compared to substrates having solvent-based primers.

EXAMPLE 11

The effect of Z-6040 on the solvent-base primer BR127 (Cytec Materials Inc., Havre de Grace, MD) was studied and the results are shown in the following table. The solvent-based primer BR127 with silane was prepared according to the method described in Example

- 48 -

4. This data shows that the addition of the silane adhesion promoter to the solvent-based primer does not improve its performance unlike the water-based primers containing silane.

EXAMPLE 12

The primer formulation (4-2) from Example 4 was used to prime grit blasted aluminum adherends. The following table shows the wedge test results for grit blasted aluminum substrates bonded together with FM®377 in the presence of a primer either with or without silane adhesion promoter present. Each of the resulting aluminum structures was exposed to 60°C with 100% relative humidity during testing. The durability of the aluminum structure with a primer containing silane is clearly demonstrated by comparison of the final crack growth compared to that of the control structure. After four weeks the structure having grit blasted aluminum with primer containing silane (4-2) had a crack length of 1.66 inches while the control structure had a crack length of 2.77 inches, a difference of over an inch. Furthermore, the crack growth of the control was over 400% more than that of the substrates prepared with the primer (4-2). The primer (4-2) of the present invention significantly improves the durability of the bonded structure.

EXAMPLE 13

The primer formulation (4-3) from Example 4 was used to prime grit blasted aluminum adherends. The following table shows the wedge test results for grit blasted aluminum substrates bonded together with FM®377 in the presence of a primer either with or without silane adhesion promoter present. Each of the resulting aluminum structures was exposed to 60°C with 100% relative humidity during testing. The durability of the aluminum structure with a primer containing silane is again clearly demonstrated by comparison of the final crack growth compared to that of the control structure. After four weeks the structure having grit blasted aluminum with primer containing silane (4-3) had a crack length of 2.29 inches while the control structure had a crack length of 2.85 inches.

EXAMPLE 14

A primer formulation is prepared according to the procedure in Example 4 for primer formulation (4-1) except that a thermosetting phenolic resin GP05555 from Georgia Pacific is substituted for the DER 669 epoxy resin. The resulting primer formulation is sprayed onto a 2024 T3 aluminum or a AM 355 steel surface. The metal sheets are bonded with an epoxy adhesive film. A wedge test is performed on each of the resulting structures and satisfactory results are obtained.

EXAMPLE 15

A primer formulation is prepared from a water dispersed phenolic thermosetting resin GP05546 from Georgia Pacific by mixing one part of a silane coupling agent per one hundred parts of the phenolic resin. The resulting primer is applied and tested as in Example 5 and satisfactory results are obtained.

EXAMPLE 16

A primer formulation is prepared according to the procedure in Example 4 for primer formulation (4-1) except that 50% of the XU 3903 epoxy resin is substituted with a Matrimid 5292 bismaleimide thermosetting resin available from Ciba-Geigy. The resulting primer is applied and tested as in Example 5 and satisfactory results are obtained.

EXAMPLE 17

A mixture of 500 g of Matrimide 5292A from Ciba-Geigy, 500 g of TM 123 resin from Shell Chemical Co. and 5g Triton B are grounded in a media mill until a particle size of less than 1 micron is obtained. With vigorous stirring, 5g of A1100 silane from OSi

- 52 -

Specialties, Inc., Danbury, CT is added. This mixture is sprayed onto aluminum sheets, which are cleaned in accordance with ASTM D2651-79G, using a DeVilbus spray gun to a thickness of 0.0003 mil. The primer is air
5 dried and allowed to cure at 180°C for 60 minutes. The metal sheets are bonded with FM®450 adhesive from Cytec Industries according to the manufacturer's instructions to give a bonded panel. Satisfactory results are obtained when testing is performed on the bonded metal
10 sheets.

EXAMPLE 18

A primer formulation is prepared according to the
15 procedure in Example 4 for primer formulation (4-1) except that PAPHEN® phenoxy waterborne dispersion PKHW® 35 resin is substituted for the DER 669 epoxy resin. The resulting primer formulation is sprayed onto a 2024 T3 aluminum or a AM 355 steel surface. The metal
20 sheets are bonded with an epoxy adhesive film. Wedge and lap shear tests are performed on each of the resulting structures and satisfactory results are obtained.

25 The compositions and processes of the present invention have numerous advantages. The compositions allow the use of an environmentally benign surface treatment process for metal surfaces and enhances bond strength, delays onset of corrosion and exhibits
30 stability in aqueous and salt laden environmental conditions. The surface treatment process also provides a relatively large processing window and minimizes failure of adhesive bonded joints. Further, excessive amounts of electricity are not required.
35 Also, the surface treatment process can be applied by spraying or brushing and does not require a large capital outlay.

- 53 -

Other variations and modifications which will be obvious to those skilled in the art can be made in the foregoing examples without departing from the spirit or scope of the invention.

What is claimed is:

1. A primer composition comprising: an aqueous dispersion of
 - (i) at least one thermosetting resin curable at an elevated temperature;
 - (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and
 - (iii) a curing agent.
2. The primer composition of claim 1, wherein said thermosetting resin is selected from the group consisting of epoxy, bismaleimide, phenolic and unsaturated polyester resins.
3. The primer composition of claim 2, wherein said thermosetting resin is selected from the group consisting of epoxy, bismaleimide and phenolic resin.
4. A primer composition comprising: an aqueous dispersion of
 - (i) at least one epoxy resin curable at an elevated temperature;
 - (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and
 - (iii) a curing agent.
5. The primer composition of claim 4, wherein said organosilane is present in an amount from about

- 0.01 to about 75 parts per hundred parts of said epoxy resin.
6. The primer composition of claim 5, wherein said organosilane is present in an amount from about 0.01 to about 30 parts per hundred parts of said epoxy resin.
 7. The primer composition of claim 4, wherein said epoxy resin has a curing temperature from about 60°C to about 200°C.
 8. The primer composition of claims 1 or 4, wherein said organosilane is selected from the group consisting of beta-(3,4-epoxycyclohexyl)ethyl trimethoxysilane, gamma-glycidoxypropyl trimethoxysilane, gamma-mercaptopropyltrimethoxy silane, gamma-aminopropyltriethoxysilane, bis-(gamma-trimethoxysilylpropyl)amine, N-phenyl-gamma-aminopropyltrimethoxysilane, and (3-glycidoxypropyl)methyldiethoxysilane.
 9. A process for preparing a composite article comprising a metal article and a layer of crosslinkable resin bonded thereto comprising:
 - (a) applying to said metal article a primer composition, comprising an aqueous dispersion of:
 - (i) at least one thermosetting resin curable at an elevated temperature; (ii) at least one organosilane, each said organosilane containing at least one hydrolyzable group; and (iii) a curing agent;
 - (b) applying a crosslinkable resin to said primed surface of said metal article; and
 - (c) curing said crosslinkable resin.

10. A primer composition comprising an aqueous dispersion of

(A) (a) a dispersed phase from about 60 to about 10 percent by weight of said aqueous dispersion and (b) an aqueous continuous phase from about 40 to about 90 percent by weight of said aqueous dispersion, and wherein an epoxy resin is present as a mixture of epoxy resins comprising:

(i) from about 30 to about 70 weight percent of a solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of from about 400 to about 800;

(ii) from about 5 to about 20 weight percent of a solid epoxy resin having an epoxy functionality of from about 1.8 to about 4 and an epoxy equivalent weight of from about 2000 to about 8000;

(iii) from about 5 to about 40 weight percent of a solid epoxy resin having an epoxy functionality of at least 5 and having an epoxy equivalent weight of from about 100 to about 400; and

said weight percents of said (i) to (iii) totaling 100 percent based on total weight of the epoxy component;

(B) at least one organosilane, each said organosilane containing at least one hydrolyzable group, said organosilane is selected from the group consisting of beta-(3,4-epoxycyclohexyl) ethyl trimethoxysilane, gamma-glycidoxypropyl trimethoxysilane, gamma-mercaptopropyltrimethoxy silane, gamma-aminopropyltriethoxysilane, bis-(gammatrimethoxysilylpropyl)amine, N-phenyl-

gammaaminopropyltrimethoxysilane, and
(3-glycidoxypropyl)methyldiethoxysilane; and

(C) an aromatic curing agent selected from the group consisting of 2,2-bis(4-[4-aminophenoxy]-phenyl)propane, 4,4'-diaminodiphenylsulfone, 3,3'-diaminodiphenylsulfone, 4,4'-diaminodiphenyl ketone, and 4,4'-[1,4-phenylene(1-methylethylidene)]bis(benzeneamine).

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 98/18092

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C09D5/00 C09D163/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C09D

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 4 056 208 A (PREJEAN GEORGE WYATT) 1 November 1977 see claims 1,7,10-14 see column 2, line 36 - column 3, line 68 ---	1-8
A	WO 94 06876 A (CYTEC TECH CORP) 31 March 1994 see claims 1-6,18-23 ---	1
A	US 4 001 154 A (SCHMIDT DONALD L) 4 January 1977 see claims 1-5 see column 3, line 2 - line 40 -----	1

☐ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

*** Special categories of cited documents :**

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

3 December 1998

Date of mailing of the international search report

14/12/1998

Name and mailing address of the ISA
